## features

- 68.8dBFS SNR
- 88dB SFDR

■ Low Power: 401mW Total

- Single 1.8V Supply
- DDR LVDS Outputs
- Easy-to-Drive 1.32VP-p Input Range
- 1.25GHz Full Power Bandwidth S/H
- Optional Clock Duty Cycle Stabilizer
- Low Power Sleep and Nap Modes
- Serial SPI Port for Configuration
- Pin-Compatible 12-Bit Version
- 40-Lead ( $6 \mathrm{~mm} \times 6 \mathrm{~mm}$ ) QFN Package

## APPLICATIONS

- Communications
- Cellular Basestations
- Software Defined Radios
- Medical Imaging
- High Definition Video
- Testing and Measurement Instruments

## DESCRIPTIOn

The LTC ${ }^{\circledR} 2153-14$ is a 310 Msps 14 -bit $\mathrm{A} / D$ converter designed for digitizing high frequency, wide dynamic range signals. It is perfectfor demanding communications applications with AC performance that includes 68.8 dB SNR and 88dB spurious free dynamic range (SFDR). The 1.25 GHz input bandwidth allows the ADC to undersample high frequencies with good performance. The latency is only five clock cycles.

DC specs include $\pm 1.2 \mathrm{LSB}$ INL (typ), $\pm 0.35$ LSB DNL (typ) and no missing codes over temperature. The transition noise is $2.11 \mathrm{LSB}_{\text {RMS }}$.
The digital outputs are double data rate (DDR) LVDS.
The ENC ${ }^{+}$and ENC- inputs can be driven differentially with a sine wave, PECL, LVDS, TTL, orCMOS inputs. An optional clock duty cycle stabilizer allows high performance at full speed for a wide range of clock duty cycles.

## TYPICAL APPLICATION

LTC2153-14 32K Point 2-Tone FFT, $\mathrm{f}_{\mathrm{IN}}=71 \mathrm{MHz}$ and 69 MHz , 310Msps

## absolute maximum ratings

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: All voltage values are with respect to GND with GND and OGND shorted (unless otherwise noted).
Note 3: When these pin voltages are taken below GND or above $V_{D D}$, they will be clamped by internal diodes. This product can handle input currents of greater than 100 mA below $G N D$ or above $\mathrm{V}_{D D}$ without latchup.
Note 4: When these pin voltages are taken below GND they will be clamped by internal diodes. When these pin voltages are taken above $V_{D D}$ they will not be clamped by internal diodes. This product can handle input currents of greater than 100 mA below GND without latchup.

Note 5: $\mathrm{V}_{\mathrm{DD}}=0 \mathrm{~V}_{\mathrm{DD}}=1.8 \mathrm{~V}, \mathrm{f}_{\text {SAMPLE }}=310 \mathrm{MHz}$, differential $\mathrm{ENC}^{+} /$ENC $^{-}=$ $2 V_{p-p}$ sine wave, input range $=1.32 V_{p-p}$ with differential drive, unless otherwise noted.
Note 6: Integral nonlinearity is defined as the deviation of a code from a best fit straight line to the transfer curve. The deviation is measured from the center of the quantization band.
Note 7: Offset error is the offset voltage measured from -0.5 LSB when the output code flickers between 00000000000000 and 11111111111111 in 2's complement output mode.
Note 8: Guaranteed by design, not subject to test.
Note 9: Recommended operating conditions.

## TYPICAL PERFORMANCG CHARACTERISTICS

## PIn fUnCTIOnS

VDD (Pins 1, 2): 1.8V Analog Power Supply. Bypass to ground with $0.1 \mu \mathrm{~F}$ ceramic capacitor. Pins 1, 2 can share a bypass capacitor.
GND (Pins 3, 6, 10, 13, 35, Exposed Pad Pin 41): ADC Power Ground. The exposed pad must be soldered to the PCB ground.
$\mathrm{A}_{\mathrm{IN}}{ }^{+}$(Pin 4): Positive Differential Analog Input.
$A_{I N}{ }^{-}$(Pin 5): Negative Differential Analog Input.
SENSE (Pin 7): Reference Programming Pin. Connecting SENSE to $V_{D D}$ selects the internal reference and a $\pm 0.66 \mathrm{~V}$ input range. An external reference between 1.23 V and 1.27 V applied to SENSE selects an input range of $\pm 0.528$ - $V_{\text {SENSE. }}$
$\mathbf{V}_{\text {REF }}$ (Pin 8): Reference Voltage Output. Bypass to ground with a $2.2 \mu \mathrm{~F}$ ceramic capacitor. Nominally 1.25 V .
$V_{\text {CM }}$ (Pin 9): Common Mode Bias Output; nominally equal to $0.439 \bullet V_{D D}$. $V_{C M}$ should be used to bias the common mode of the analog inputs. Bypass to ground with a $0.1 \mu \mathrm{~F}$ ceramic capacitor.

ENC ${ }^{+}$(Pin 11): Encode Input. Conversion starts on the rising edge.

ENC- (Pin 12): Encode Complement Input. Conversion starts on the falling edge.

OV ${ }_{\text {DD }}$ (Pins 20, 30): 1.8V Output Driver Supply. Bypass to ground with a $0.1 \mu \mathrm{~F}$ ceramic capacitor.
OGND (Pin 21): LVDS Driver Ground.
SDO (Pin 36): Serial Interface Data Output. In serial programming mode, (PAR/SER $=0 \mathrm{~V})$, SDO is the optional serial interface data output. Data on SDO is read back from the mode control registers and can be latched on the falling edge of SCK. SDO is an open-drain N-channel MOSFET output that requires an external $2 k$ pull-up resistor from 1.8 V to 3.3 V . If readback from the mode control registers is not needed, the pull-up resistor is not necessary and SDO can be left unconnected.

SDI (Pin 37): Serial Interface Data Input. In serial programming mode, $(P A R / \overline{S E R}=0 V), S D I$ is the serial interface data input. Data on SDI is clocked into the mode control registers on the rising edge of SCK. In parallel programming mode (PAR/ $\left.\overline{S E R}=V_{D D}\right)$, SDI selects 3.5 mA or 1.75 mA LVDS output current (see Table 2).

## PIn functions

SCK (Pin 38): Serial Interface Clock Input. In serial programming mode, (PAR/SER = OV), SCK is the serial interface clock input. In parallel programming mode (PAR/ $\left.\overline{S E R}=V_{D D}\right)$, SCK controls the sleep mode (see Table 2).
$\overline{\text { CS }}$ (Pin 39): Serial Interface Chip Select Input. In serial programming mode, $(\operatorname{PAR} / \overline{S E R}=0 \mathrm{~V})$, $\overline{\mathrm{CS}}$ is the serial interface chip select input. When $\overline{\text { CS }}$ is low, SCK is enabled for shifting data on SDI into the mode control registers. In parallel programming mode $\left(\operatorname{PAR} / \overline{S E R}=\mathrm{V}_{\mathrm{DD}}\right)$, CS controls the clock duty cycle stabilizer (see Table 2).
PAR/SER (Pin 40): Programming Mode Selection Pin. Connect to ground to enable the serial programming mode. $\overline{C S}$, SCK, SDI and SDO become a serial interface that control the $\mathrm{A} / \mathrm{D}$ operating modes. Connect to $\mathrm{V}_{D D}$ to enable the parallel programming mode where $\overline{\mathrm{CS}}, \mathrm{SCK}$ and SDI become parallel logic inputs that control a reduced set of the A/D operating modes. PAR/SER should be connected directly to ground or the $V_{D D}$ of the part and not be driven by a logic signal.

## LVDS Outputs (DDR LVDS)

The following pins are differential LVDS outputs. The output current level is programmable. There is an optional internal $100 \Omega$ termination resistor between the pins of each LVDS output pair.
$D_{01} 1^{-} / D_{0-1}{ }^{+}$to $D_{12-13}{ }^{-} / D_{12 \_13}{ }^{+}$(Pins 16/17, $18 / 19$, 22/23, 24/25, 28/29, 31/32, 33/34): Double-Data Rate Digital Outputs. Two data bits are multiplexed onto each differential output pair. The even data bits (D0, D2, D4, D6, D8, D10, D12) appear when CLKOUT+ is low. The odd data bits (D1, D3, D5, D7, D9, D11, D13) appear when CLKOUT+ is high.
CLKOUT-, CLKOUT+ (Pins 26, 27): Data Output Clock. The digital outputs normally transition at the same time as the falling and rising edges of CLKOUT+. The phase of $\mathrm{CLKOUT}^{+}$can also be delayed relative to the digital outputs by programming the mode control registers.
OF-, OF ${ }^{+}$(Pins 14, 15): Over/Underflow Digital Output. OF ${ }^{+}$is high when an overflow or underflow has occurred. This underflow is valid only when CLKOUT+ is low. In the second half clock cycle, the overflow is set to 0 .

## fUnCTIONAL BLOCK DIAGRAM

Figure 1. Functional Block Diagram

## timing diagrams

Double Data Rate Output Timing, All Outputs Are Differential LVDS

SPI Port Timing (Readback Mode)

SPI Port Timing (Write Mode)

## APPLLCATIONS InFORMATION

## CONVERTER OPERATION

The LTC2153-14 is a 14 -bit 310 Msps A/D converter powered by a single 1.8 V supply. The analog inputs must be driven differentially. The encode inputs should be driven differentially for optimal performance. The digital outputs are double data rate LVDS. Additional features can be chosen by programming the mode control registers through a serial SPI port.

## ANALOG INPUT

The analog input is a differential CMOS sample-andhold circuit (Figure 2). The input must be driven differentially around a common mode voltage set by the $\mathrm{V}_{\mathrm{CM}}$ output pin, which is nominally $0.439 \bullet \mathrm{~V}_{\mathrm{DD}}$. For the 1.32 V input range, the input should swing from $\mathrm{V}_{\mathrm{CM}}-0.33 \mathrm{~V}$ to $\mathrm{V}_{\mathrm{CM}}+0.33 \mathrm{~V}$. There should be $180^{\circ}$ phase difference between the inputs.

Figure 2. Equivalent Input Circuit. Only One of Two Analog Channels Is Shown

## INPUT DRIVE CIRCUITS

## Input Filtering

If possible, there should be an RC lowpass filter right at the analog inputs. This lowpass filter isolates the drive circuitry from the A/D sample-and-hold switching, and also limits wide band noise from the drive circuitry. Figure 3 shows an example of an input RC filter. The RC component values should be chosen based on the application's specific input frequency.

## Transformer-Coupled Circuits

Figure 3 shows the analog input being driven by an RF transformer with the common mode supplied through a pair of resistors via the $\mathrm{V}_{\mathrm{CM}}$ pin.

At higher input frequencies a transmission line balun transformer (Figures 4 and 5) has better balance, resulting in lower A/D distortion.

Figure 3. Analog Input Circuit Using a Transformer.
Recommended for Input Frequencies from 5 MHz to 70 MHz

Figure 4. Recommended Front-End Circuit for Input Frequencies from 15MHz to 150MHz

## APPLICATIONS InFORMATION

Figure 5. Recommended Front-End Circuit for Input Frequencies from 150 MHz to 900 MHz

Figure 6. Front-End Circuit Using a High Speed Differential Amplifier

Figure 7. Reference Circuit

## Amplifier Circuits

Figure 6 shows the analog input being driven by a high speed differential amplifier. The output of the amplifier is AC coupled to the A/D so the amplifier's output common mode voltage can be optimally set to minimize distortion.

At very high frequencies an RF gain block will often have lower distortion than a differential amplifier. If the gain block is single-ended, then a transformer circuit (Figures 3 and 5) should convert the signal to differential before driving the $A / D$. The $A / D$ cannot be driven single-ended.

## Reference

The LTC2153-14 has an internal 1.25V voltage reference. For a 1.32 V input range with internal reference, connect SENSE to $\mathrm{V}_{\mathrm{DD}}$. For a 1.32 V input range with an external reference, apply a 1.25 V reference voltage to SENSE (Figure 7).

## Encode Input

The signal quality of the encode inputs strongly affects the $A / D$ noise performance. The encode inputs should be treated as analog signals-do not route them next to digital traces on the circuit board.
The encode inputs are internally biased to 1.2 V through 10k equivalent resistance (Figure 8). If the common mode of the driver is within 1.1 V to 1.5 V , it is possible to drive the encode inputs directly. Otherwise a transformer or

Figure 8. Equivalent Encode Input Circuit

## APPLICATIONS InFORMATION

coupling capacitors are needed (Figures 9 and 10). The maximum (peak) voltage of the input signal should never exceed $\mathrm{V}_{\mathrm{DD}}+0.1 \mathrm{~V}$ or go below -0.1 V .

## Clock Duty Cycle Stabilizer

For good performance the encode signal should have a $50 \%( \pm 5 \%)$ duty cycle. If the optional clock duty cycle stabilizer circuit is enabled, the encode duty cycle can vary from 30\% to 70\% and the duty cycle stabilizer will maintain a constant $50 \%$ internal duty cycle. The duty cycle stabilizer is enabled via SPI Register A2 (see Table 3) or by $\overline{\mathrm{CS}}$ in parallel programming mode.
For applications where the sample rate needs to be changed quickly, the clock duty cycle stabilizer can be disabled. In
this case, care should be taken to make the clock a 50\% $( \pm 5 \%)$ duty cycle.

## DIGITAL OUTPUTS

The digital outputs are double-data rate LVDS signals. Two data bits are multiplexed and output on each differential output pair. There are seven LVDS output pairs (D0_1+/D0_1- through D12_13/D12_13+). Overflow ( $\mathrm{OF}^{+} / \mathrm{OF}^{-}$) and the data output clock (CLKOUT+/CLKOUT ${ }^{-}$) each have an LVDS output pair.
By default the outputs are standard LVDS levels: 3.5 mA output current and a 1.25 V output common mode voltage.

Figure 9. Sinusoidal Encode Drive

Figure 10. PECL or LVDS Encode Drive

## APPLICATIONS InFORMATION

## Programmable LVDS Output Current

The default output driver current is 3.5 mA . This current can be adjusted by serially programming mode control register A3 (see Table 3). Available current levels are $1.75 \mathrm{~mA}, 2.1 \mathrm{~mA}, 2.5 \mathrm{~mA}, 3 \mathrm{~mA}, 3.5 \mathrm{~mA}, 4 \mathrm{~mA}$ and 4.5 mA .

## Optional LVDS Driver Internal Termination

In most cases, using just an external $100 \Omega$ termination resistor will give excellent LVDS signal integrity. In addition, an optional internal $100 \Omega$ termination resistor can be enabled by serially programming mode control register A3. The internal termination helps absorb any reflections caused by imperfect termination at the receiver. When the internal termination is enabled, the output driver current is doubled to maintain the same output voltage swing.

## Overflow Bit

The overflow output bit (OF) outputs a logic high when the analog input is either overranged or underranged. The overflow bit has the same pipeline latency as the data bits.

When CLKINV is set to 0 in the SPI register A2, the OF signal is valid when CLKOUT+ is low, as shown in the Timing Diagrams section.

## Phase Shifting the Output Clock

To allow adequate set-up and hold time when latching the output data, the CLKOUT+ signal may need to be phase shifted relative to the data output bits. Most FPGAs have this feature; this is generally the best place to adjust the timing.
Alternatively, the ADC can also phase shift the CLKOUT + / CLKOUT- signals by serially programming mode control register A2. The output clock can be shifted by $0^{\circ}, 45^{\circ}$, $90^{\circ}$, or $135^{\circ}$. To use the phase shifting feature the clock duty cycle stabilizer must be turned on. Another control register bit can invert the polarity of CLKOUT ${ }^{+}$and CLKOUT-, independently of the phase shift. The combination of these two features enables phase shifts of $45^{\circ}$ up to $315^{\circ}$ (Figure 11).

Figure 11. Phase Shifting CLKOUT

## APPLICATIONS INFORMATION

## DATA FORMAT

Table 1 shows the relationship between the analog input voltage, the digital data output bits and the overflow bit. By default the output data format is offset binary. The 2's complement format can be selected by serially programming mode control register A4.

Table 1. Output Codes vs Input Voltage

| $\mathrm{A}_{\text {IN }^{+}}-\mathrm{A}_{\text {IN }}{ }^{-}$ <br> (1.32V Range) | OF | D13-DO <br> (OFFSET BINARY) | D13-DO <br> (2's COMPLEMENT) |
| :--- | :---: | :---: | :---: |

## Digital Output Randomizer

Interference from the A/D digital outputs is sometimes unavoidable. Digital interference may be from capacitive or inductive coupling or coupling through the ground plane. Even a tiny coupling factor can cause unwanted tones in the ADC output spectrum. By randomizing the digital output before it is transmitted off chip, these unwanted tones can be randomized which reduces the unwanted tone amplitude.

The digital output is randomized by applying an exclu-sive-OR logic operation between the LSB and all other data output bits. To decode, the reverse operation is applied-an exclusive-OR operation is applied between the LSB and all other bits. The LSB, OF and CLKOUT outputs are not affected. The output randomizer is enabled by serially programming mode control register A4.

Figure 12. Functional Equivalent of Digital Output Randomizer

Figure 13. Decoding a Randomized Digital Output Signal

## APPLICATIONS InFORMATION

## Alternate Bit Polarity

Another feature that may reduce digital feedback on the circuit board is the alternate bit polarity mode. When this mode is enabled, all of the odd bits (D1, D3, D5, D7, D9, $\mathrm{D} 11, \mathrm{D} 13$ ) are inverted before the output buffers. The even bits (D0, D2, D4, D6, D8, D10, D12), OF and CLK0UT are not affected. This can reduce digital currents in the circuit board ground plane and reduce digital noise, particularly for very small analog input signals.
The digital output is decoded at the receiver by inverting the odd bits (D1, D3, D5, D7, D9, D11, D13.) The alternate bit polarity mode is independent of the digital output ran-domizer-either both or neither function can be on at the same time. The alternate bit polarity mode is enabled by serially programming mode control register A4.

## Digital Output Test Patterns

To allow in-circuit testing of the digital interface to the $A / D$, there are several test modes that force the $A / D$ data outputs ( $\mathrm{OF}, \mathrm{D} 13$ to D 0 ) to known values:

All 1s: All outputs are 1
All Os: All outputs are 0
Alternating: Outputs change from all 1 s to all Os on alternating samples
Checkerboard: Outputschange from 101010101010101 to 010101010101010 on alternating samples.
The digital output test patterns are enabled by serially programming mode control register A4. When enabled, the test patterns override all other formatting modes: 2's complement, randomizer, alternate-bit polarity.

## Output Disable

The digital outputs may be disabled by serially programming mode control register A3. All digital outputs including OF and CLKOUT are disabled. The high impedance disabled state is intended for long periods of inactivity, it is not designed for multiplexing the data bus between multiple converters.

## Sleep Mode

The A/D may be placed in sleep mode to conserve power. In sleep mode the entire A/D converter is powered down, resulting in $<5 \mathrm{~mW}$ power consumption. If the encode input signal is not disabled the power consumption will be higher (up to 5 mW at 310 MHz ). Sleep mode is enabled by mode control register A1 (serial programming mode), or by SCK (parallel programming mode).
The amount of time required to recover from sleep mode depends on the size of the bypass capacitor on $V_{\text {REF }}$. For the suggested value in Figure 1, the A/D will stabilize after $0.1 \mathrm{~ms}+2500 \bullet \mathrm{t}_{\mathrm{p}}$ where $\mathrm{t}_{\mathrm{p}}$ is the period of the sampling clock.

## Nap Mode

In nap mode the A/D core is powered down while the internal reference circuits stay active, allowing faster wake-up. Recovering from nap mode requires at least 100 clock cycles. Nap mode is enabled by setting register A1 in the serial programming mode.
Wake-up time from nap mode is guaranteed only if the clock is kept running, otherwise sleep mode wake-up conditions apply.

## DEVICE PROGRAMMING MODES

The operating modes of the LTC2153-14 can be programmed by either a parallel interface or a simple serial interface. The serial interface has more flexibility and can program all available modes. The parallel interface is more limited and can only program some of the more commonly used modes.

## Parallel Programming Mode

To use the parallel programming mode, PAR/ $\overline{\mathrm{SER}}$ should be tied to $V_{D D}$. The $\overline{C S}$, SCK and SDI pins are binary logic inputs that set certain operating modes. These pins can be tied to $\mathrm{V}_{\mathrm{DD}}$ or ground, or driven by $1.8 \mathrm{~V}, 2.5 \mathrm{~V}$, or 3.3 V CMOS logic. Table 2 shows the modes set by $\overline{\mathrm{CS}}$, SCK and SDI.

## APPLICATIONS INFORMATION

Table 2. Parallel Programming Mode Control Bits $\left(\right.$ PAR/SER $\left.=V_{D D}\right)$

| PIN | DESCRIPTION |
| :--- | :--- |
| $\overline{\text { CS }}$ | Clock Duty Cycle Stabilizer Control Bit |
|  | $0=$ Clock Duty Cycle Stabilizer Off |
|  | $1=$ Clock Duty Cycle Stabilizer On |
| SCK | Power Down Control Bit |
|  | $0=$ Normal Operation |

| SDI | LVDS Current Selection Bit |
|  | $0=3.5 m A$ LVDS Current Mode |
|  | $1=1.75 m A$ LVDS Current Mode |

## Serial Programming Mode

To use the serial programming mode, PAR/ $\overline{\mathrm{SER}}$ should be tied to ground. The CS, SCK, SDI and SDO pins become a serial interface that program the $A / D$ control registers. Data is written to a register with a 16-bit serial word. Data can also be read back from a register to verify its contents.
Serial data transfer starts when $\overline{\mathrm{CS}}$ is taken low. The data on the SDI pin is latched at the first sixteen rising edges of SCK. Any SCK rising edges after the first sixteen are ignored. The data transfer ends when $\overline{\mathrm{CS}}$ is taken high again.
The first bit of the 16 -bit input word is the $R / \bar{W}$ bit. The next seven bits are the address of the register (A6:A0). The final eight bits are the register data (D7:D0).
If the $R / \bar{W}$ bit is low, the serial data ( $D 7: D 0$ ) will be written to the register set by the address bits (A6:AO). If the $R / \bar{W}$ bit is high, data in the register set by the address bits (A6:AO) will be read back on the SDO pin (see the Timing Diagrams). During a readback command the register is not updated and data on SDI is ignored.

The SDO pin is an open-drain output that pulls to ground with a $200 \Omega$ impedance. If register data is read back through SDO, an external 2 k pull-up resistor is required. If serial data is only written and readback is not needed, then SDO can be left floating and no pull-up resistor is needed. Table 3 shows a map of the mode control registers.

## Software Reset

If serial programming is used, the mode control registers should be programmed as soon as possible after the power supplies turn on and are stable. The first serial command must be a software reset which will reset all register data bits to logic 0 . To perform a software reset it is necessary to write 1 in register A0 (Bit D7). After the reset is complete, Bit D7 is automatically set back to zero. This register is write-only.

## GROUNDING AND BYPASSING

The LTC2153-14 requires a printed circuit board with a clean unbroken ground plane in the first layer beneath the ADC. A multilayer board with an internal ground plane is recommended. Layout for the printed circuit board should ensure that digital and analog signal lines are separated as much as possible. In particular, care should be taken not to run any digital track alongside an analog signal track or underneath the ADC.
High quality ceramic bypass capacitors should be used at the $V_{D D}, O V_{D D}, V_{C M}, V_{R E F}$ pins. Bypass capacitors must be located as close to the pins as possible. Size 0402 ceramic capacitors are recommended. The traces connecting the pins and bypass capacitors must be kept short and should be made as wide as possible.

The analog inputs, encode signals, and digital outputs should not be routed next to each other. Ground fill and grounded vias should be used as barriers to isolate these signals from each other.

## HEAT TRANSFER

Most of the heat generated by the LTC2153-14 is transferred from the die through the bottom-side exposed pad and package leads onto the printed circuit board. For good electrical and thermal performance, the exposed pad must be soldered to a large grounded pad on the PC board. This pad should be connected to the internal ground planes by an array of vias.
