

dsPIC30F5015/5016 Rev. A0 Silicon Errata

The dsPIC30F5015/5016 (Rev. A0) samples you have received were found to conform to the specifications and functionality described in the following documents:

- DS70157 "dsPIC30F/33F Programmer's Reference Manual"
- DS70149 "dsPIC30F5015/5016 Data Sheet"
- DS70046 "dsPIC30F Family Reference Manual"

The exceptions to the specifications in the documents listed above are described in this section. These exceptions are described for the specific devices listed below:

- dsPIC30F5015
- dsPIC30F5016

These devices may be identified by the following message that appears in the MPLAB® ICD 2 Output Window under MPLAB IDE, when a "Reset and Connect" operation is performed within MPLAB IDE:

Setting Vdd source to target
Target Device dsPIC30F5016 found,
revision = Rev A0
...Reading ICD Product ID
Running ICD Self Test
...Passed
MPLAB ICD 2 Ready

The errata described in this section will be addressed in future revisions of dsPIC30F5015 and dsPIC30F5016 devices.

Silicon Errata Summary

The following list summarizes the errata described in this document:

1. DISI Instruction

The DISI instruction will not disable interrupts if a DISI instruction is executed in the same instruction cycle that the DISI counter decrements to zero.

2. Output Compare Module

The output compare module will produce a glitch on the output when an I/O pin is initially set high and the module is configured to drive the pin low at a specified time.

3. Output Compare Module in PWM Mode

Output compare will produce a glitch when loading 0% duty cycle in PWM mode. It will also miss the next compare after the glitch.

4. Quadrature Encoder Interface Module

The Index Pulse Reset mode of the QEI does not work properly when used along with count error detection. When counting upwards, the POSCNT register will increment one extra count after the index pulse is received. The extra count will generate a false count error interrupt.

5. INT0, ADC and Sleep Mode

ADC event triggers from the INT0 pin will not wake-up the device from Sleep mode if the SMPI bits are non-zero.

6. 10-bit ADC: Sampling Rate

The 10-bit Analog-to-Digital Converter (ADC) has a maximum sampling rate of 750 ksps.

7. Quadrature Encoder Interface (QEI) Module

The QEI module does not generate an interrupt in a particular overflow condition.

8. Sleep Mode

Execution of the Sleep instruction (PWRSAV #0) may cause incorrect program operation after the device wakes up from Sleep. The current consumption during Sleep may also increase beyond the specifications listed in the device data sheet.

9. I²C™ Module

When the I²C module is enabled, the dsPIC[®] DSC device generates a glitch on the SDA and SCL pins, causing a false communication start in a single-master configuration or a bus collision in a multi-master configuration.

10. I²C Module

The I^2C module loses incoming data bytes when operating as an I^2C slave.

 Motor Control PWM – PWM Counter Register
 PTMR does not continue counting down after halting code execution in Debug mode. 12. I/O Port - Port Pin Multiplexed with IC1

The Port I/O pin multiplexed with the Input Capture 1 (IC1) function cannot be used as a digital input pin when the UART auto-baud feature is enabled.

13. I²C Module

After enabling the I^2C module (I2CEN = 1), the S and P bit values are not correct.

14. I²C Module: 10-bit addressing mode

When the I²C module is configured for 10-bit addressing using the same address bits (A10 and A9) as other I²C device A10 and A9 bits may not work as expected.

15. Timer Module

Clock switching prevents the device from waking up from Sleep.

The following sections describe the errata and work around to these errata, where they may apply.

1. Module: DISI Instruction

When a user executes a DISI #7, for example, this will disable interrupts for 7 + 1 cycles (7 + the DISI instruction itself). In this case, the DISI instruction uses a counter which counts down from 7 to 0. The counter is loaded with 7 at the end of the DISI instruction.

If the user code executes another <code>DISI</code> on the instruction cycle where the <code>DISI</code> state machine does not properly re-engage and continue to disable interrupts. At this point, all interrupts are enabled. The next time the user code executes a <code>DISI</code> instruction, the feature will act normally and block interrupts.

In summary, it is only when a DISI execution is coincident with the current DISI count = 0, that the issue occurs. Executing a DISI instruction before the DISI counter reaches zero will not produce this error. In this case, the DISI counter is loaded with the new value, and interrupts remain disabled until the counter becomes zero.

Work around

When executing multiple DISI instructions within the source code, make sure that subsequent DISI instructions have at least one instruction cycle between the time that the DISI counter decrements to zero and the next DISI instruction. Alternatively, make sure that subsequent DISI instructions are called before the DISI counter decrements to zero.

2. Module: Output Compare Module

A glitch will be produced on an output compare pin under the following conditions:

- The user software initially drives the I/O pin high using the output compare module or a write to the associated PORT register.
- The output compare module is configured and enabled to drive the pin low at some later time (OCxCON = 0x0002 or OCxCON = 0x0003).

When these events occur, the output compare module will drive the pin low for one instruction cycle (TCY) after the module is enabled.

Work around

None. However, the user may use a Timer interrupt and write to the associated PORT register to control the pin manually.

3. Module: Output Compare in PWM Mode

If the desired duty cycle is '0' (OCxRS = 0), the module will generate a high level glitch of 1 Tcy. The second problem is that on the next cycle after the glitch, the OC pin does not go high, or in other words, it misses the next compare for any value written on OCxRS.

Work around

There are two possible solutions to this problem:

- Load a value greater than '0' to the OCxRS register when operating in PWM mode. In this case, no 0% duty cycle is achievable.
- If the application requires 0% duty cycles, the output compare module can be disabled for 0% duty cycles, and re-enabled for non-zero percent duty cycles.

4. Module: Quadrature Encoder Interface

The Index Pulse Reset mode of the QEI does not work properly when used along with count error detection. When counting upwards, the POSCNT register will increment one extra count after the index pulse is received. The extra count will generate a false count error interrupt.

Work around

There are multiple work arounds for this issue, depending on the specific requirements of the application:

- Ignore count error interrupts when the counting direction is upwards and the POSCNT register has the value of MAXCNT + 1.
- 2. The user may disable count error interrupts by setting the CEID bit in the DFLTCON register.
- 3. The user may disable the index pulse reset feature by clearing the POSRES bit (QEICON<2>). Writing QEICON = 0x0600 will provide a QEI interrupt each time an index pulse is received, but the POSCNT register will not be modified. The POSCNT register value can be read in the QEI interrupt handler and used as an offset value to calculate the absolute position of the encoder disc with respect to the index pulse.

5. Module: INTO, ADC and Sleep Mode

ADC event triggers from the INT0 pin will not wake-up the device from Sleep mode if the SMPI bits are non-zero. This means that if the ADC is configured to generate an interrupt after a certain number of INT0 triggered conversions, the ADC conversions will not be triggered and the device will remain in Sleep. The ADC will perform conversions and wake-up the device only if it is configured to generate an interrupt after each INT0 triggered conversion (SMPI<3:0> = 0000).

Work around

None. If ADC event trigger from the INT0 pin is required, initialize SMPI<3:0> TO '0000' (interrupt on every conversion).

6. Module: 10-bit ADC: Sampling Rate

The maximum sampling rate for the 10-bit Analog-to-Digital Conversion module is 750 ksps.

This rate is only achievable when one A/D pin is being used. Configuring the ADC module to use multiple sample-and-hold circuits (see device data sheet) will not improve the conversion speed of the module.

Table 1 shows the maximum ADC conversion rates possible using the 10-bit ADC module and the corresponding module configuration and operating conditions.

TABLE 1: 10-BIT ADC RATE PARAMETERS

dsPIC30F 10-bit ADC Conversion Rates						
A/D Speed	TAD Minimum	Sampling Time Min	Rs Max	VDD	Temperature	A/D Channels Configuration
Up to 750 ksps	95.24 ns	2 TAD	500Ω	4.5V to 5.5V	-40°C to +85°C	ANX CHX ADC
Up to 500 ksps	153.85 ns	1 TAD	5.0 kΩ	4.5V to 5.5V	-40°C to +125°C	ANX CHX ADC ANX Or VINEF-
Up to 300 ksps	256.41 ns	1 TAD	5.0 kΩ	3.0V to 5.5V	-40°C to +125°C	ANX CHX ADC ANX Or VREF-

Work around

None.

7. Module: QEI Interrupt Generation

The Quadrature Encoder Interface (QEI) module does not generate an interrupt when MAXCNT is set to 0xFFFF and the following events occur:

- 1. POSCNT underflows from 0x0000 to 0xFFFF.
- 2. POSCNT stops.
- 3. POSCNT overflows from 0xFFFF to 0x0000.

This sequence of events occurs when the motor is running in one direction, which causes POSCNT to underflow to 0xFFFF. Once this happens, the motor stops and starts to run in the opposite direction, which generates an overflow from 0xFFFF to 0x0000. The QEI module does not generate an interrupt when this condition occurs.

Work around

To prevent this condition from occurring, set MAXCNT to 0x7FFF, which will cause an interrupt to be generated by the QEI module.

In addition, a global variable could be used to keep track of bit 15, so that when an overflow or underflow condition is present on POSCNT, the variable will toggle bit 15. Example 1 shows the code required for this global variable.

EXAMPLE 1:

8. Module: Sleep Mode

Execution of the Sleep instruction (PWRSAV #0) may cause incorrect program operation after the device wakes up from Sleep. The current consumption during Sleep may also increase beyond the specifications listed in the device data sheet.

Work arounds

To avoid this issue, any of the following three work arounds can be implemented, depending on the application requirements.

Work around 1:

Ensure that the PWRSAV #0 instruction is located at the end of the last row of Program Flash Memory available on the target device and fill the remainder of the row with NOP instructions.

This can be accomplished by replacing all occurrences of the PWRSAV #0 instruction with a function call to a suitably aligned subroutine. The address() attribute provided by the MPLAB ASM30 assembler can be utilized to correctly align the instructions in the subroutine. For an application written in C, the function call would be GotoSleep(), while for an assembly language application, the function call would be CALL GotoSleep.

The Address Error Trap Service Routine software can then replace the invalid return address saved on the stack with the address of the instruction immediately following the $_\texttt{GotoSleep}$ or GotoSleep() function call. This ensures that the device continues executing the correct code sequence after waking up from Sleep mode.

Example 2 demonstrates the work around described above, as it would apply to a dsPIC30F5015 device.

EXAMPLE 2:

```
.global __reset
.global _main
.global _GotoSleep
.global ___AddressError
.global __INT1Interrupt
   .section *, code
main:
         INTCON2, #INT1EP ; Set up INT pins to detect falling edge
       IFS1, #INT1IF ; Clear interrupt pin interrupt flag bits
IEC1, #INT1IE ; Enable ISR processing for INT pins
  BCLR
  BSET IEC1, #INT1IE
        _GotoSleep
  CALL
                      ; Call function to enter SLEEP mode
continue:
  BRA _continue
 ______
; Address Error Trap
 AddressError:
  BCLR INTCON1, #ADDRERR
   ; Set program memory return address to _continue
  POP.D WO
  MOV.B #tblpage (continue), W1
  MOV
        #tbloffset (_continue), W0
  PUSH.D WO
  RETFIE
: ------
 INT1Interrupt:
                        ; Ensure flag is reset
  BCLR IFS1, #INT1IF
  RETETE
                          ; Return from Interrupt Service Routine
   .section *, code, address (0xAFC0)
GotoSleep:
; fill remainder of the last row with NOP instructions
   .rept 31
     NOP
   .endr
; Place SLEEP instruction in the last word of program memory
  PWRSAV #0
```

Work around 2:

Instead of executing a PWRSAV #0 instruction to put the device into Sleep mode, perform a clock switch to the 512 kHz Low-Power RC (LPRC) Oscillator with a 64:1 postscaler mode. This enables the device to operate at 0.002 MIPS, thereby significantly reducing the current consumption of the device. Similarly, instead of using an interrupt to wake-up the device from Sleep mode, perform another clock switch back to the original oscillator source to resume normal operation. Depending on the device, refer to Section 7. "Oscillator" (DS70054) or Section 29. "Oscillator" (DS70268) in the "dsPIC30F Family Reference Manual" (DS70046) for more details on performing a clock switch operation.

Note: The above work around is recommended for users for whom application hardware changes are not possible.

Work around 3:

Instead of executing a PWRSAV #0 instruction to put the device into Sleep mode, perform a clock switch to the 32 kHz Low-Power (LP) Oscillator with a 64:1 postscaler mode. This enables the device to operate at 0.000125 MIPS, thereby significantly reducing the current consumption of the device. Similarly, instead of using an interrupt to wake-up the device from Sleep mode, perform another clock switch back to the original oscillator source to resume normal operation. Depending on the device, refer to Section 7. "Oscillator" (DS70054) or Section 29. "Oscillator" (DS70268) in the "dsPIC30F Family Reference Manual" (DS70046) for more details on performing a clock switch operation.

Note: The above work around is recommended for users for whom application hardware changes are possible, and also for users whose application hardware already includes a 32 kHz LP Oscillator crystal.

9. Module: I²C Module

When the I²C module is enabled by setting the I2CEN bit in the I2CCON register, the dsPIC DSC device generates a glitch on the SDA and SCL pins. This glitch falsely indicates "Communication Start" to all devices on the I²C bus, and can cause a bus collision in a multi-master configuration.

Work arounds

To avoid this issue, any of the following two work arounds can be implemented, depending on the application requirements.

Work around 1:

In a single-master environment, add a delay between enabling the I^2C module and the first data transmission. The delay should be equal to or greater than the time it takes to transmit two data bits.

In the multi-master configuration, in addition to the delay, all other I^2C masters should be synchronized and wait for the I^2C module to be initialized before initiating any kind of communication.

Work around 2:

Add external hardware, such as a high-speed tri-state non-inverting buffer with an enable input, which can be connected to the SDA and SCL pins and enabled/disabled using the dsPIC DSC device port I/O.

Use the following procedure to implement this work around:

- Disable the external buffer using the dsPIC DSC device port I/O.
- 2. Set up and enable the I²C module.
- Enable the external buffer using the dsPIC DSC device port I/O.

10. Module: I²C Module

When the I^2C module is configured as a slave, either in single-master or multi-master mode, the I^2C receiver buffer is filled whether a valid slave address is detected or not. Therefore, an I^2C receiver overflow condition occurs and this condition is indicated by the I2COV flag in the I2CSTAT register.

This overflow condition inhibits the ability to set the I^2C receive interrupt flag (SI2CF) when the last valid data byte is received. Therefore, the I^2C slave Interrupt Service Routine (ISR) is not called and the I^2C receiver buffer is not read prior receiving the next data byte.

Work arounds

To avoid this issue, either of the following two work arounds can be implemented, depending on the application requirements.

Work around 1:

For applications in which the I²C receiver interrupt is not required, the following procedure can be used to receive valid data bytes:

- 1. Wait until the RBF flag is set.
- 2. Poll the I²C receiver interrupt SI2CIF flag.
- 3. If SI2CF is not set in the corresponding Interrupt Flag Status (IFSx) register, a valid address or data byte has not been received for the current slave. Execute a dummy read of the I²C receiver buffer, I2CRCV; this will clear the RBF flag. Go back to step 1 until SI2CF is set and then continue to Step 4.
- If the SI2CF is set in the corresponding Interrupt Flag Status (IFSx) register, valid data has been received. Check the D_A flag to verify that an address or a data byte has been received.
- Read the I2CRCV buffer to recover valid data bytes. This will also clear the RBF flag.
- 6. Clear the I²C receiver interrupt flag SI2CF.
- 7. Go back to step 1 to continue receiving incoming data bytes.

Work around 2:

Use this work around for applications in which the I²C receiver interrupt is required. Assuming that the RBF and the I2COV flags in the I2CSTAT register are set due to previous data transfers in the I2C bus (i.e., between master and other slaves); the following procedure can be used to receive valid data bytes:

- When a valid slave address byte is detected, SI2CF bit is set and the I²C slave interrupt service routine is called; however, the RBF and I2COV bits are already set due to data transfers between other I²C nodes.
- 2. Check the status of the D_A flag and the I2COV flag in the I2CSTAT register when executing the I²C slave service routine.
- 3. If the D_A flag is cleared and the I2COV flag are set, an invalid data byte was received but a valid address byte was received. The overflow condition occurred because the I²C receive buffer was overflowing with previous I²C data transfers between other I²C nodes. This condition only occurs after a valid slave address was detected.
- 4. Clear the I2COV flag and perform a dummy read of the I²C receiver buffer, I2CRCV, to clear the RBF bit and recover the valid address byte. This action will also avoid the loss of the next data byte due to an overflow condition.
- Verify that the recovered address byte matches the current slave address byte. If they match, the next data to be received is a valid data byte.
- If the D_A flag and the I2COV flag are both set, a valid data byte was received and a previous valid data byte was lost. It will be necessary to code for handling this overflow condition.

11. Module: Motor Control PWM – PWM Counter Register

If the PTDIR bit is set (when PTMR is counting down), and the CPU execution is halted (after a breakpoint is reached), PTMR will start counting up as if PTDIR was zero.

Work around

None.

12. Module: I/O Port – Port Pin Multiplexed with IC1

If the user application enables the auto-baud feature in the UART module, the I/O pin multiplexed with the IC1 (Input Capture) pin cannot be used as a digital input.

Work around

None.

13. Module: I²C Module

After enabling the I^2C module (I2CEN = 1), the S and P bits are set to '1' and '0' values, respectively. This means that there is some communication going on the bus and the I^2C module must wait for the bus to become Idle. In this case, the I^2C module will continue to wait for the bus to become Idle until it receives a STOP instruction.

Work arounds

Depending on your environment, the two following work arounds can be used.

Work around 1:

In a single-master environment, add a delay between enabling the $\rm I^2C$ module and the first data transmission. The delay should be equal to or greater than the time it takes to transmit two data bits. In the multi-master configuration, in addition to the delay, all other $\rm I^2C$ masters should be synchronized, and wait for the $\rm I^2C$ module to be initialized before initiating any kind of communication.

Work around 2:

In dsPIC DSC devices in which the I²C module is multiplexed with other modules that have precedence in the use of the pin, it is possible to avoid this issue by enabling the higher priority module before enabling the I²C module.

Use the following procedure to implement this work around:

- Enable the higher priority peripheral module that is multiplexed on the same pins as the I²C module.
- 2. Set up and enable the I²C module.
- Disable the higher priority peripheral module that was enabled in step 1.

Note:

Work around 2 works only for devices that share the SDA and SCL pins with another peripheral that has a higher precedence over the port latch, such as the UART. The priority is shown in the pin diagram located in the data sheet. For example, if the SDA and SCL pins are shared with the UART and SPI pins, and the UART has higher precedence on the port latch pin.

14. Module: I²C Module

If there are two I²C devices on the bus, one of them is acting as the Master receiver and the other as the Slave transmitter. Suppose that both devices are configured for 10-bit addressing mode, and have the same value in the A10 and A9 bits of their addresses. When the Slave select address is sent from the Master, both the Master and Slave acknowledges it. When the Master sends out the read operation, both the Master and the Slave enter into Read mode and both of them transmit the data. The resultant data will be the ANDing of the two transmissions.

Work around

Use different addresses including the higher two bits (A10 and A9) for different modules.

15. Module: Timer Module

When the timer is being operated in the asynchronous mode using the secondary oscillator (32.768 kHz) and the device is put into Sleep mode, a clock switch to any other oscillator mode before putting the device to Sleep prevents the timer from waking the device from Sleep.

Work around

Do not clock switch to any other oscillator mode if the timer is being used in the asynchronous mode using the secondary oscillator (32.768 kHz).

APPENDIX A: REVISION HISTORY

Revision A (09/2005)

Original version of the document.

Revision B (05/2006)

Added silicon issues 3 (Output Compare Module in PWM Mode) and 4 (Quadrature Encoder Interface Module).

Revision C (9/2006)

Added silicon issues 1 and 6.

Revision D (3/2007)

Added silicon issue 7.

Revision E (9/2007)

Added silicon issues 8 (QEI) and 9 (Sleep Mode).

Revision F (12/2007)

Added silicon issues 10 and 11 (I2C Module), 12 (Motor Control PWM – PWM Counter Register), and 13 (I/O Port – Port Pin Multiplexed with IC1).

Revision G (5/2008)

Added silicon issues 13 and 14 (I2C Module), and 15 (Timer Module). Removed silicon issue 3 (Using OSC2/RC15 pin for Digital I/O).

NOTES:

Note the following details of the code protection feature on Microchip devices:

- · Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

QUALITY MANAGEMENT SYSTEM

CERTIFIED BY DNV

ISO/TS 16949:2002

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELOQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.
