## Functional Description

### 1. Block description

#### 1.1. Active Control

In the case of segment mode, controls the selection or deselection of the chip. Following a LP signal input, and after the select signal is input, a select signal is generated internally until 160 bits of data have been read in. Once data input has been completed, a select signal for cascade connection is output, and the chip is deselected.

In the case of common mode, controls the input/output data of bidirectional pins.

#### 1.2. SP Conversion & Data Control

In the case of segment mode, keep input data which are 2 clocks of XCK at 4-bit parallel mode into latch circuit, or keep input data which are 1 clock of XCK at 8-bit parallel mode into latch circuit, after that they are put on the internal data bus 8 bits at a time.

#### 1.3. Data Latch Control

In the case of the segment mode, it selects the state of the data latch, which reads in the data bus signals. The shift direction is controlled by the control logic and for every 16 bits of data read in, the selection signal shifts one bit, based on the state of the control circuit.

#### 1.4. Data Latch

In the case of the segment mode, it latches the data on the data bus. The latched state of each LCD driver output pin is controlled by the control logic and the data latch control 160 bits of data are read in 20 sets of 8 bits.

#### 1.5. Line Latch / Shift Register

In the case of the segment mode, all 160 bits which have been read into the data latch, are simultaneously latched on to the falling edge of the LP signal, and output to the level shift block.

In the case of the common mode, shifts data from the data input pin on to the falling edge of the LP signal.

#### 1.6. Level Shifter

The logic voltage signal is level-shifted to the LCD driver voltage level, and output to the driver block.

#### 1.7. 4-Level Driver

It drives the LCD driver output pins from the line latch/shift register data, selecting one of 4 levels ( $V_0$ ,  $V_{12}$ ,  $V_{43}$ ,  $V_{ss}$ ) based on the S/C, FR and  $\overline{\text{DISPOFF}}$  signals.

#### 1.8. Control Logic

It controls the operation of each block. In the case of the segment mode, when an LP signal has been input, all blocks are reset and the control logic waits for the selection signal output from the active control block. Once the selection signal has been output, operation of the data latch and data transmission are controlled, 160 bits of data are read in, and the chip is deselected.

In the case of the common mode, it controls the direction of the data shift.

**2. LCD Driver Output Voltage Level**

The relationship amongst the data bus signal, AC converted signal FR and LCD driver output voltage is as shown in the table below:

**2.1. Segment Mode**

FR	Latch Data	$\overline{\text{DISPOFF}}$	Driver Output Voltage Level (Y1 - Y160)
L	L	H	V43
L	H	H	V5
H	L	H	V12
H	H	H	V0
X	X	L	V5

Here,  $V_{SS} \leq V_5 < V_{43} < V_{12} < V_0$ , H: VDD (+2.5 to +5.5V), L: VSS (0V), X: Don't care

**2.2. Common Mode**

Here,  $V_{SS} \leq V_5 < V_{43} < V_{12} < V_0$ , H: VDD (+2.5 to +5.5V), L: VSS (0V), X: Don't care

Note: There are two kinds of power supply (logic level voltage, LCD driver voltage) for the LCD driver. Please supply regular voltage, which assigned by specification for each power pin.

That time "Don't care" should be fixed to "H" or "L", avoiding floating.

### 7. Precaution

Be careful when connecting or disconnecting the power

This LSI has a high-voltage LCD driver, so it may be permanently damaged by a high current, which may occur, if a voltage is supplied to the LCD driver power supply while the logic system power supply is floating.

The details are as follows:

- When connecting the power supply, connect the LCD driver power after connecting the logic system power. Furthermore, when disconnecting the power, disconnect the logic system power after disconnecting the LCD driver power.
- We recommend that you connect a serial resistor (50-100Ω) or fuse to the LCD driver power  $V_0$  of the system as a current limiting device. Also, set a suitable value for the resistor in consideration of the LCD display grade.

In addition, when connecting the logic power supply, the logic condition of the LSI inside is insecure. Therefore connect the LCD driver power supply after resetting logic condition of this LSI inside on  $\overline{\text{DISPOFF}}$  function. After that, the  $\overline{\text{DISPOFF}}$  cancel the function after the LCD driver power supply has become stable. Furthermore, when disconnecting the power, set the LCD driver output pins to level  $V_{SS}$  on the  $\overline{\text{DISPOFF}}$  function. After that, disconnect the logic system power after disconnecting the LCD driver power.

When connecting the power supply, follow the recommended sequence shown.

### Cautions concerning storage:

- When storing the product, it is recommended that it be left in its shipping package. After the seal of the packing bag has been broken, store the products in a nitrogen atmosphere.
- Storage conditions :

Storage state	Storage conditions
unopened ( <b>less than 90 days</b> )	Temperature: 5 to 30°C ; humidity: 80%RH or less
After seal of broken ( <b>less than 30 days</b> )	Room temperature, dry nitrogen atmosphere

- Don't store in a location exposed to corrosive gas or excessive dust.
- Don't store in a location exposed to direct sunlight of subject to sharp changes in temperature.
- Don't store the product such that it is subjected to an excessive load weight, such as by stacking.
- Deterioration of the plating may occur after long-term storage, so special care is required. It is recommended that the products be inspected before use.
