Functional Description

The CY7S1061G is a high-performance CMOS fast static RAM organized as 1,048,576 words by 16 bits. This device features fast access times (10 ns) and a unique ultra-low power Deep Sleep mode. With Sleep mode currents as low as 22 μA , the CY7S1061G device combines the best features of fast and low-power SRAM in industry-standard package options. The device also features embedded ECC^[1]. ECC logic can detect and correct single-bit error in the accessed location. The CY7S1061GE device includes an ERR pin that signals an error-detection and correction event during a read cycle

To access devices with a single-chip enable input, assert the chip enable input (CE) LOW. To access dual chip enable devices, assert both chip enable inputs – CE₁ as LOW and CE₂ as HIGH.

To perform data writes, assert the Write Enable (\overline{WE}) input LOW, and provide the data and address on device data pins (I/O₀ through I/O₁₅) and address pins (A₀ through A₁₉) respectively. The Byte High Enable (BHE) and Byte Low Enable (BLE) inputs control byte writes, and write data on the corresponding I/O lines to the memory location specified. BHE controls I/O₈ through I/O₁₅ and BLE controls I/O₀ through I/O₇.

To perform data reads, assert the Output Enable (\overline{OE}) input and provide the required address on the address lines. Read data is accessible on the I/O lines (I/O₀ through I/O₁₅). You can perform byte accesses by asserting the required byte enable signal (BHE or BLE) to read either the upper byte or the lower byte of data from the specified address location.

All I/Os (I/O₀ through I/O₁₅) are placed in a high-impedance state when the device is deselected (\overline{CE} HIGH for single chip enable devices and \overline{CE}_1 HIGH and \overline{CE}_2 LOW for dual chip enable devices), or the control signals (\overline{OE} , BLE, BHE) are de-asserted.

The device is placed in a low power Deep Sleep mode when the Deep Sleep pin (\overline{DS}) is LOW. In this state, the device is disabled for normal operation and is placed in a data retention mode. The device can be activated by de-asserting the Deep Sleep pin (\overline{DS} HIGH).

The CY7S1061G is available in 48-pin TSOP I, 54-pin TSOP II, and 48-ball VFBGA packages.

Notes

- Test conditions assume signal transition time (rise/fall) of 3 ns or less, timing reference levels of 1.5 V (for V_{CC} ≥ 3 V) and V_{CC}/2 (for V_{CC} < 3 V), and input pulse levels of 0 to 3 V (for V_{CC} ≥ 3 V), and 0 to V_{CC} (for V_{CC} < 3 V). Test conditions for the read cycle use the output loading shown in part (a) of Figure 5 on page 7, unless specified otherwise.
- t_{POWER} gives the minimum amount of time that the power supply is at stable V_{CC} until the first memory access is performed.
- t_{HZOE}, t_{HZCE}, t_{HZBE}, t_{LZOE}, t_{LZCE}, t_{LZWE}, and t_{LZBE} are specified with a load capacitance of 5 pF, as shown in part (b) of Figure 5 on page 7. Transition is measured ±200 mV from steady state voltage.
- At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE}, t_{HZBE} is less than t_{LZBE}, t_{HZOE} is less than t_{LZOE}, and t_{HZWE} is less than t_{LZWE} for any device.
- For all dual chip enable devices, CE is the logical combination of CE₁ and CE₂. When CE₁ is LOW and CE₂ is HIGH, CE is LOW; when CE₁ is HIGH or CE₂ is LOW, CE is HIGH.
- These parameters are guaranteed by design and are not tested.
- The internal write time of the memory is defined by the overlap of $\overline{WE} = V_{IL}$, $\overline{CE} = V_{IL}$, and \overline{BHE} or $\overline{BLE} = V_{IL}$. These signals must be LOW to initiate a write, and the HIGH transition of any of these signals can terminate the operation. The input data setup and hold timing should be referenced to the edge of the signal that terminates the write.
- The minimum write pulse width for Write Cycle No. 2 (\overline{WE} controlled, \overline{OE} LOW) should be the sum of t_{HZWE} and t_{SD}.

41. The input voltage levels on these pins should be either at V_{IH} or V_{IL}.

42. V_{IL} on \overline{DS} must be ≤ 0.2 V.

43. This mode does not guarantee data retention. Power cycling needs to be performed for the device to return to normal operation.

FAST SRAM^[44] Errata Summary

This table defines the errata applicability to available 16-Mbit devices.

Items	Part Numbers	Silicon Rev	Fix Status
FAST SRAM ^[44] does not meet 10-ns speed-in AC switching parameters as specified in the datasheet specifications.	CY7S1061G30 CY7S1061GE30	*A	Fixed devices to be available from April 11, 2014.

■ Problem Definition

CY7S1061G30 and CY7S1061GE30 do not meet 10-ns speed in AC switching parameters as specified in [Table 1](#).

■ Parameters Affected

AC switching parameters

■ Trigger Condition

Functionality is not guaranteed when the device is operated at speed of 10 ns.

■ Scope of Impact

This issue may not pose problems for most end systems because they may incorporate some margin to the datasheet specifications. The deviation from the datasheet specified limit of 10 ns is 2 ns.

■ Workaround

The RAM controller timing needs additional margin to accommodate the slower speed.

■ Fix Status

The fix for the above issue is in progress. Fixed devices will be available from April 11, 2014.

Note

44. This applies to all MPNs mentioned in [Part Numbers Affected](#).
